# The TRAPPIST-1 System is Observationally Favorable and a High Priority Target for JWST

- Seven known Earth-sized planets (Gillon et al. 2016; 2017; Luger et al. 2017)
- Transiting a small ( $0.12 R_{\odot}$ ) and cool (2500 K) late M dwarf (Van Grootel et al. 2018)
- Only 12.2 pc away
- Planets unlikely to have low mean molecular weight atmospheres (de Wit et al. 2016; 2018; Moran et al. 2018)

# Detecting water in a habitable atmosphere

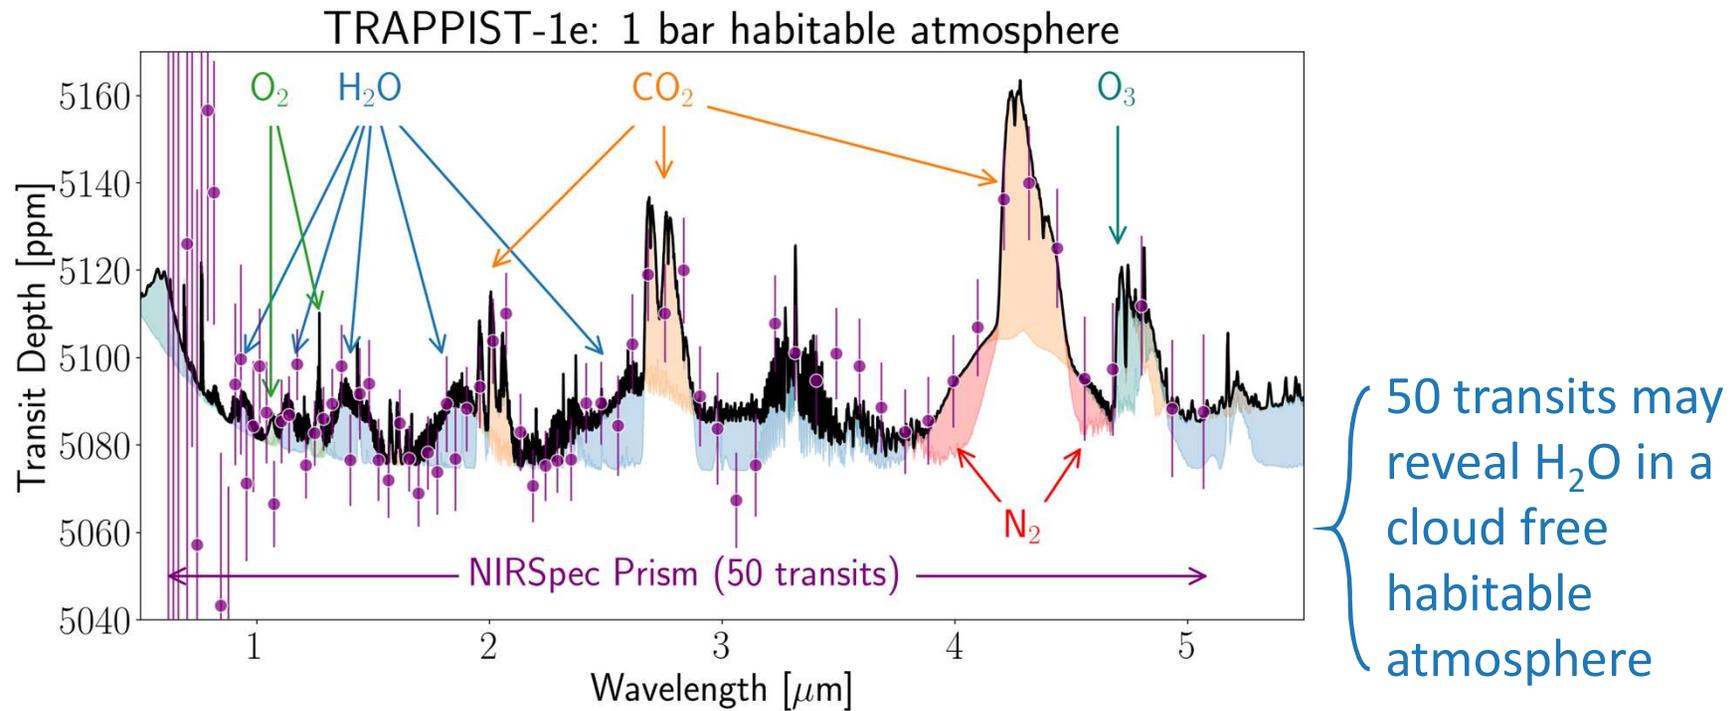

Lustig-Yaeger et al. (2019)

# Detecting water in a habitable atmosphere may be difficult

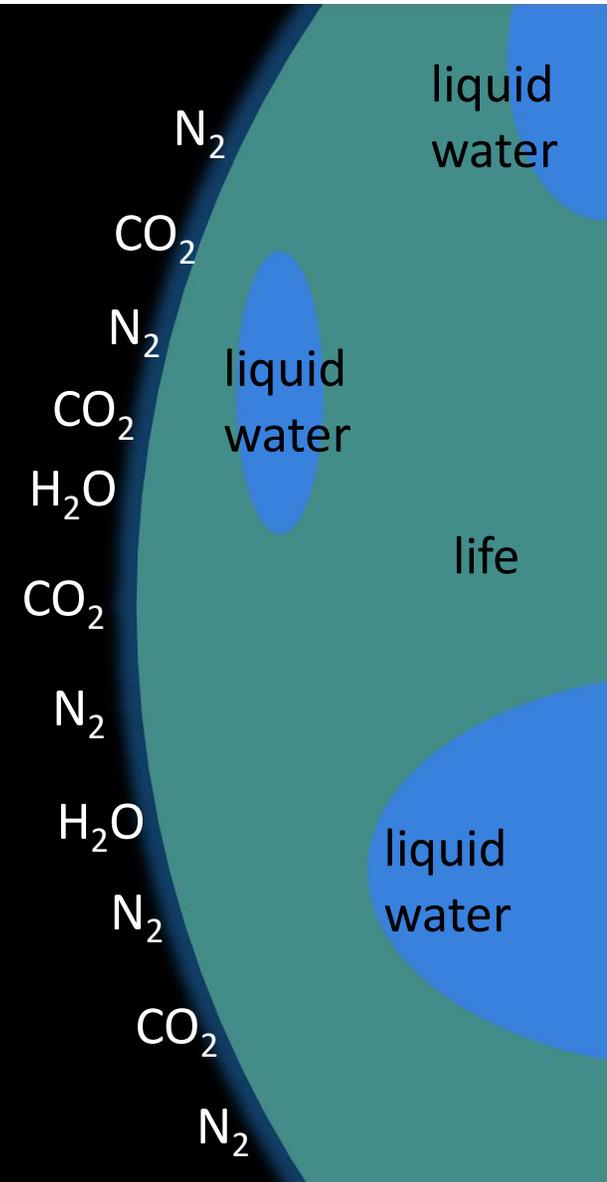

Detecting water in a habitable atmosphere may be difficult, and will depend on clouds

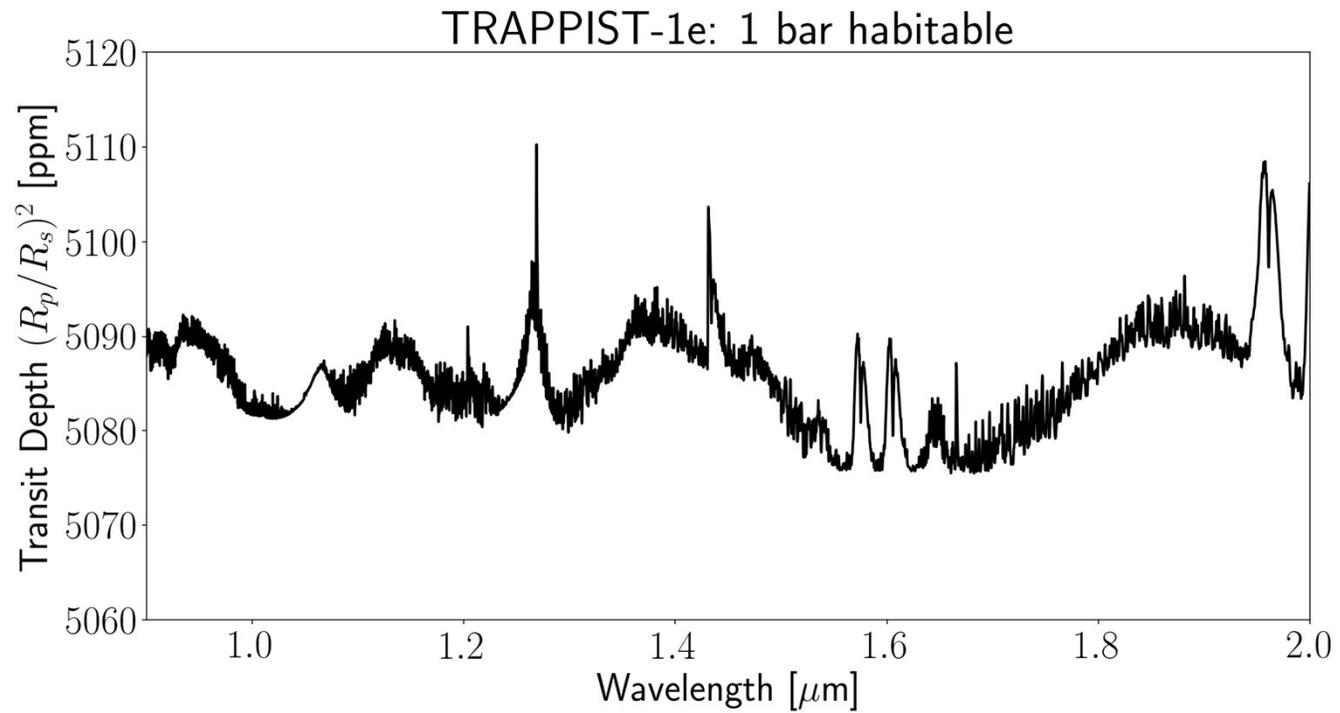

# Detecting water in a habitable atmosphere may be difficult, and will depend on clouds

Can JWST determine if the TRAPPIST-1 HZ planets are currently *inhabited*?

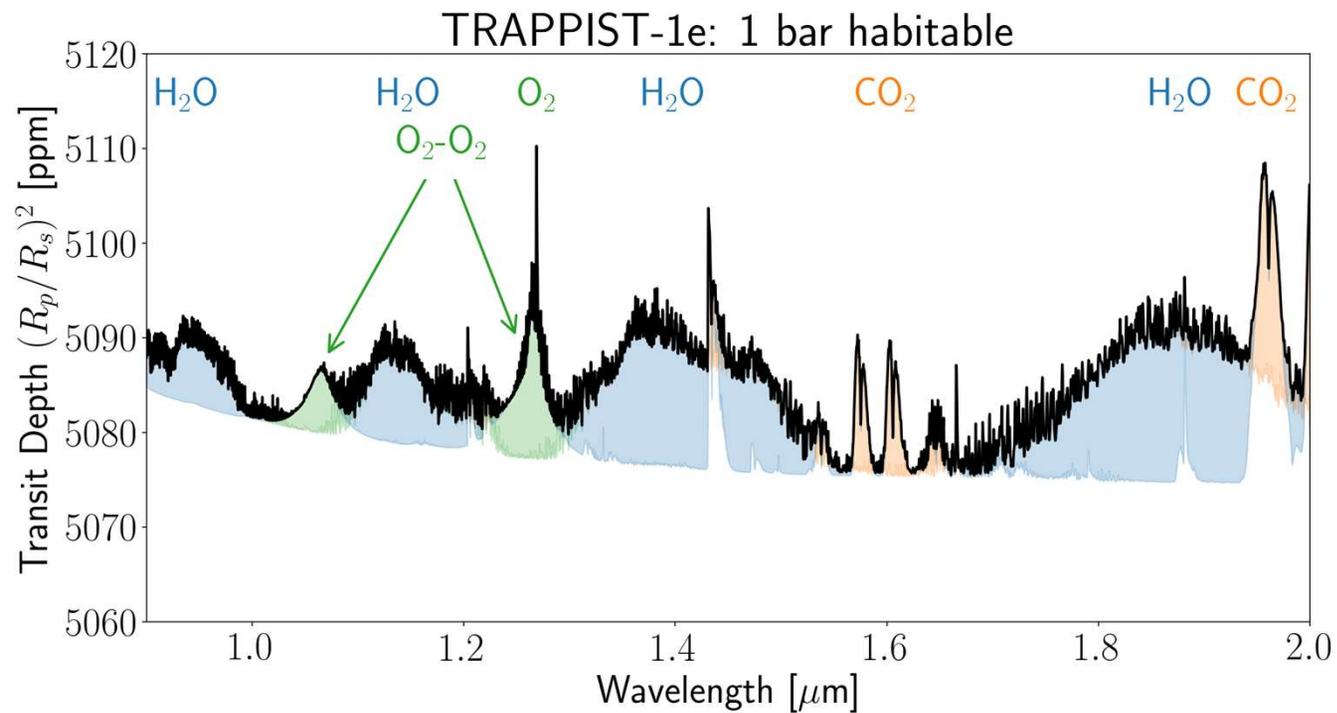

# Detecting Modern Earth levels of O<sub>2</sub>

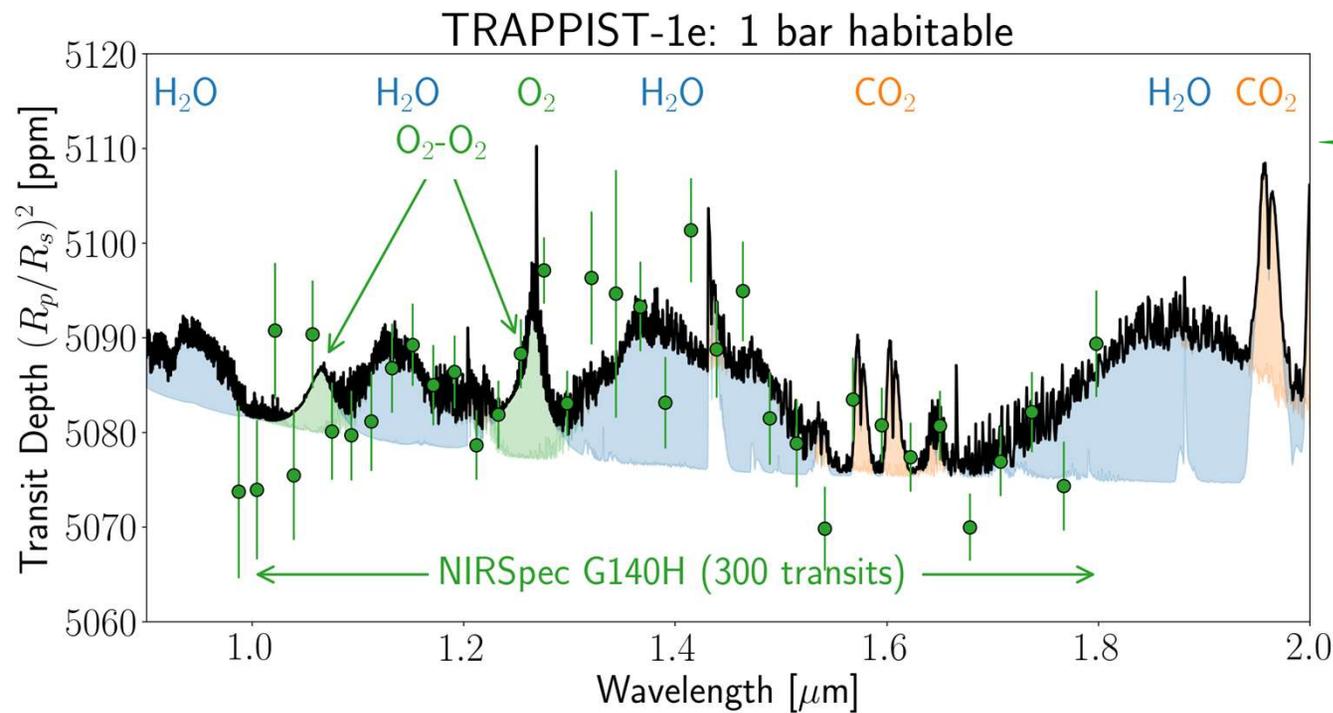

Lustig-Yaeger et al. (2019)

# Detecting Modern Earth levels of O<sub>2</sub>

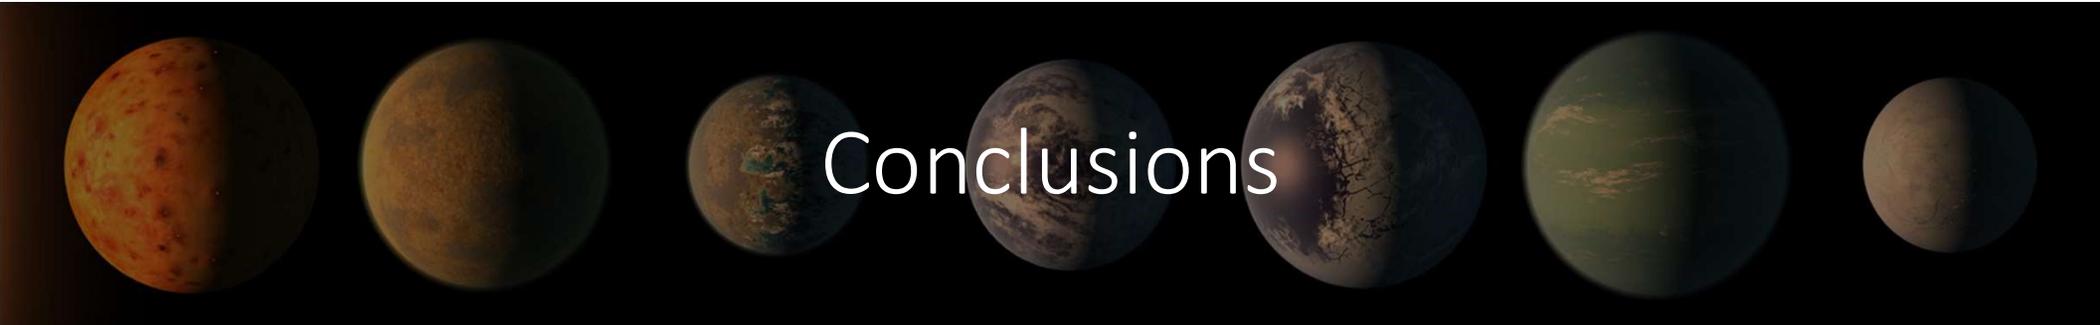

Lustig-Yaeger et al. (2019)

# Detecting Modern Earth levels of O<sub>2</sub> may be infeasible

300 transits are needed to reveal 20% O<sub>2</sub> in a 1 bar N<sub>2</sub>-dominated atmosphere

## Conclusions

- JWST should be able to **detect** different plausible terrestrial atmospheres for all of the TRAPPIST-1 planets in about 10 transits, but up to 30 transits may be required if **clouds** are present
- **CO<sub>2</sub>** is a strong spectroscopic indicator of a terrestrial atmosphere, but a weak discriminator between atmospheric compositions
- **H<sub>2</sub>O** as a weak indicator of habitability may be detectable for TRAPPIST-1e if the terminator has << 100% cloud coverage
- **O<sub>2</sub>** as a biosignature is unlikely to be detectable with JWST, but **O<sub>4</sub> (O<sub>2</sub>-O<sub>2</sub> CIA)** may be detectable and would indicate an O<sub>2</sub>-dominated post-ocean-loss atmosphere
